

## ***Insurance Logistic Regression***

## Introduction

In this document we explore logistic techniques to estimate the probability that a person will crash their car and a model to estimate the cost in the event of the crash. We will be using the Insurance data set to build logistic regression models to predict car crashes. This data set contains approximately 8100 records. Each record represents a customer at an auto insurance company and has two target variables. The first target variable, TARGET\_FLAG, is a 1 or a 0. A “1” means that the person was in a car crash. A zero means that the person was not in a car crash. The second target variable is TARGET\_AMT. This value is zero if the person did not crash their car. But if they did crash their car, this number will be a value greater than zero. In order to create a model that most accurately predicts the number of car crashes, we will prepare the data using imputation, capping, and binning, and we will select the variables using stepwise automated variable selection. We will present several models, discuss the merits and shortcomings of each, and ultimately select one model that best predicts which customers are most likely to crash their cars.

## Data Exploration

The dataset contains approximately 8161 records with 23 variables with the combination of categorical and the continuous variables. Dataset also contains 2 target variables and an index variable. First we will focus on predicting the TARGET\_FLAG variable which signifies whether or not customer crashed his/her car. Based on the value of TARGET\_FLAG then we calculate the TARGET\_AMT which is a second target variable and signifies the cost of the crash.

Table1 shows the list of variables included in the dataset and proposed effect of each variable on the response variable is also shown in the table. Dictionary seems to be the right place to start as it has been prepared and the data matches with the description of these variables. Data contains both the categorical and continuous variables. It also makes sense to validate some of these urban legends and the theories that certain variables can have more effect on the response variable. It will also help to consider some of these proposed effects when we impute the data. Some of these variables may be highly correlated with each other or some sort of relationship between them. One variable of such that is the INCOME and the HOME\_VAL as people with high income tend to have larger or expensive homes.

**Table 1: Data Dictionary with Theoretical Effect**

VARIABLE NAME	DEFINITION	THEORETICAL EFFECT
INDEX	Identification Variable (do not use)	None
TARGET_FLAG	Was Car in a crash? 1=YES 0=NO	None
TARGET_AMT	Cost of the crash	None
AGE	Age of Driver	Very young people tend to be risky. Maybe very old people also.
BLUEBOOK	Value of Vehicle	Unknown effect on probability of collision, but probably effect the payout if there is a crash
CAR_AGE	Vehicle Age	Unknown effect on probability of collision, but probably effect the payout if there is a crash
CAR_TYPE	Type of Car	Unknown effect on probability of collision, but probably effect the payout if there is a crash
CAR_USE	Vehicle Use	Commercial vehicles are driven more, so might increase probability of collision
CLM_FREQ	#Claims(Past 5 Years)	The more claims you filed in the past, the more you are likely to file in the future
EDUCATION	Max Education Level	Unknown effect, but in theory more educated people tend to drive more safely
HOMEKIDS	#Children @Home	Unknown effect
HOME_VAL	Home Value	In theory, home owners tend to drive more responsibly
INCOME	Income	In theory, rich people tend to get into fewer crashes
JOB	Job Category	In theory, white collar jobs tend to be safer
KIDSDRIV	#Driving Children	When teenagers drive your car, you are more likely to get into crashes
MSTATUS	Marital Status	In theory, married people drive more safely
MVR_PTS	Motor Vehicle Record Points	If you get lots of traffic tickets, you tend to get into more crashes
OLDCLAIM	Total Claims(Past 5 Years)	If your total payout over the past five years was high, this suggests future payouts will be high
PARENT1	Single Parent	Unknown effect
RED_CAR	A Red Car	Urban legend says that red cars (especially red sports cars) are more risky. Is that true?
REVOKED	License Revoked (Past 7 Years)	If your license was revoked in the past 7 years, you probably are a more risky driver.
SEX	Gender	Urban legend says that women have less crashes then men. Is that true?
TIF	Time in Force	People who have been customers for a long time are usually more safe.
TRAVTIME	Distance to Work	Long drives to work usually suggest greater risk
URBANICITY	Home/Work Area	Unknown
YOJ	Years on Job	People who stay at a job for a long time are usually more safe

Next we will look at the descriptive statistics of the dataset. Some of the variables are showing high scales compared to most of the other variables in the dataset, so we may have to transform these variables during the preparation phase. All the variables in the dataset are continuous.

**Table 2: Data Statistics**

	count	mean	std	min	25%	50%	75%	max
<b>index</b>	8161.0	5151.867663	2978.893962	1.0	2559.0	5133.0	7745.0	10302.00000

Table 3 shows the summary of the missing values in the training dataset. Six of the variables, AGE, YOJ, INCOME, HOME\_VAL, JOB and CAR\_AGE, have missing data. We will create two new variables in this process; one with the IMP\_\* prefix for the imputed variable, leaving the original variable untouched, and one with the m\_\* prefix as an indicator variable for the imputed variable. Sometimes, the fact that a variable was missing can actually be predictive. This means the indicator variables might be entered into the predictive model. JOB variable is a categorical variable and has the missing data, instead of creating a new variable, we will replace the missing values with “Missing Job Info” new category. Remaining all other variables will be imputed with their median value as it less prone to the outliers.

**Table 3: Missing Values**

dtype:	int64

Next I have created the correlation matrix with the strongest correlated variables, shown in Figure 1. It is interesting to observe that MVR\_PTS and CLM\_FREQ higher correlation and it makes sense as the customer with high number of traffic tickets prone to more crashes or claims. Same applies to the HOMEKIDS and KIDSDRIV, the more kids are at home, the possibility of kids driving the vehicle is high. Rest of the continuous variables seems to be fairly independent and that further proves that this data might prepared well before.

Figure 1: Variables with Strongest Correlation Matrix

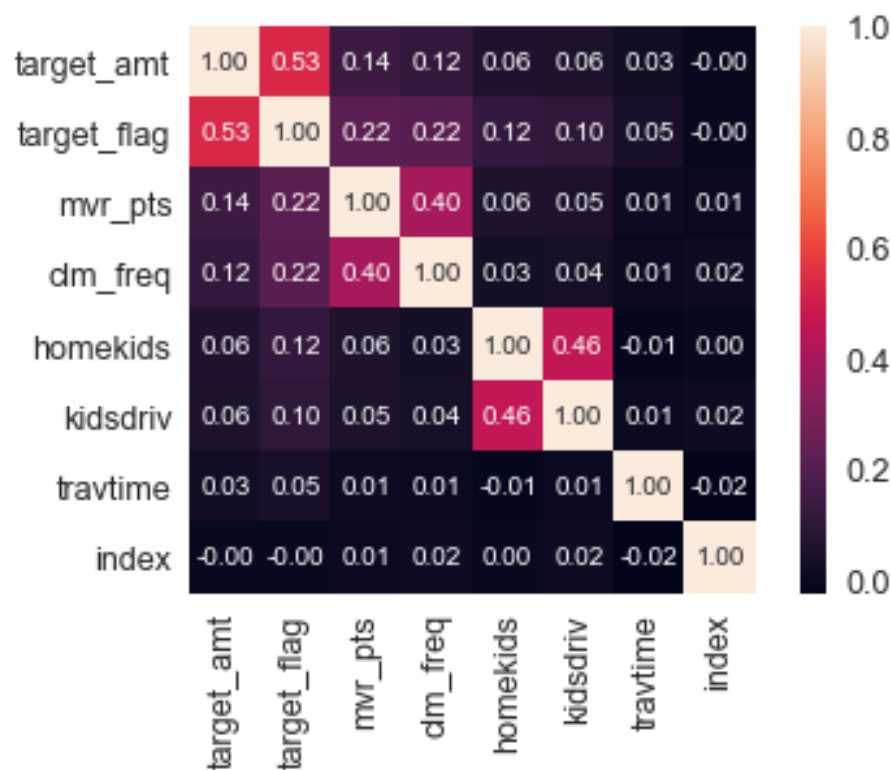

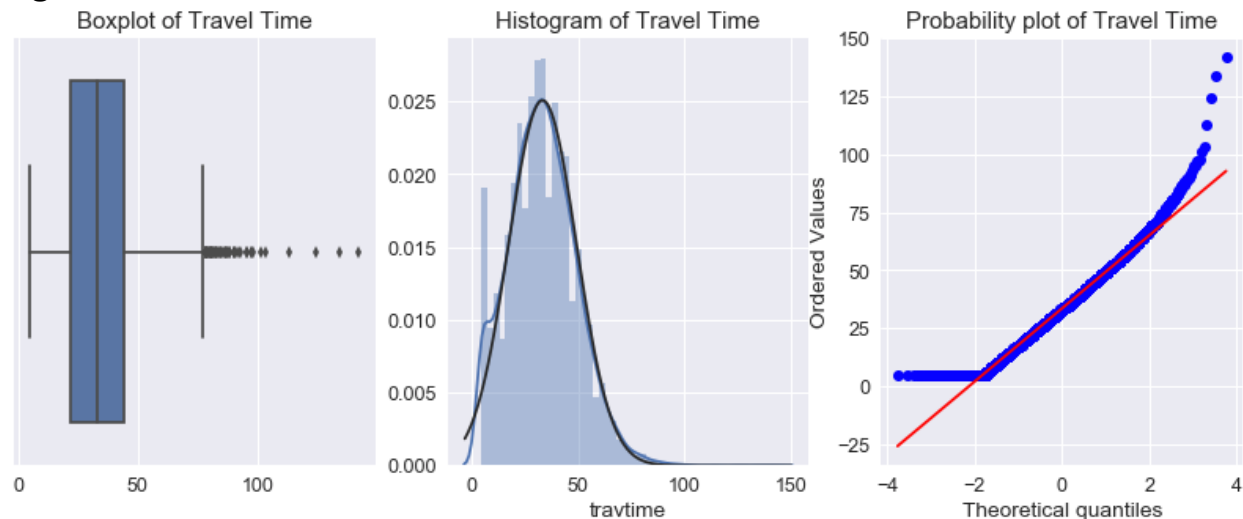

Figure 2: Correlation Matrix

So next, I have started with the continuous variables first. Some of these variables have an extreme values and resulting highly skewed distribution. Figure 3 shows the distribution of TRAVTIME for the customer. For this variable data seems to be fairly close to the normal distribution and the number of outliers that will imputed are shown in the figure as well. TRAVTIME had a reported commute time of over two hours and twenty minutes, which could be a mistake, but is otherwise skewing the data.

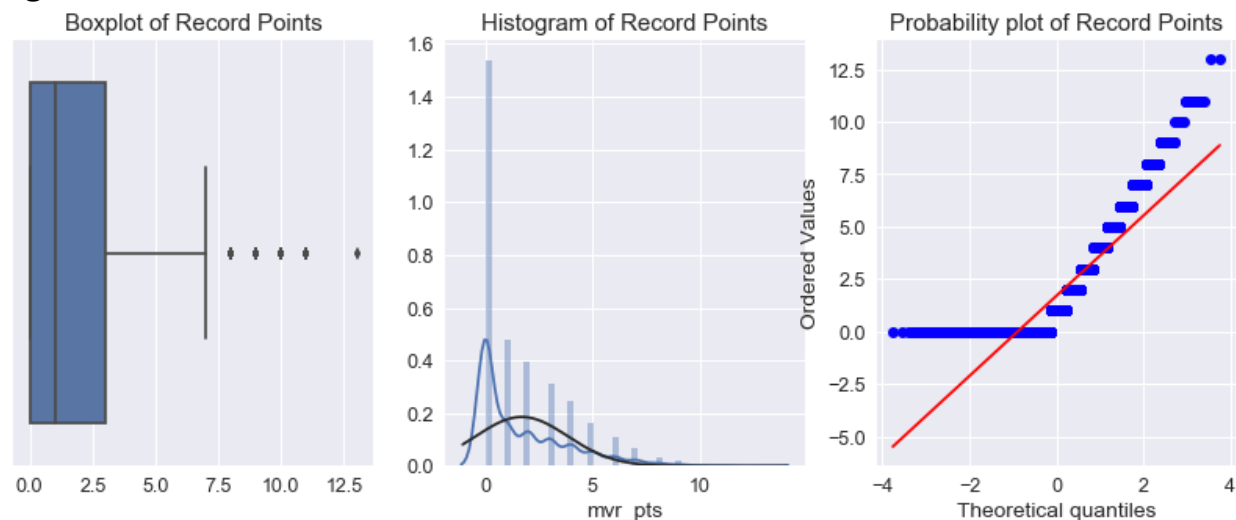

**Figure 3: Travel Time**

Outliers for Travel Time: [113, 124, 142, 134]

Figure 4 shows the distribution and the outliers for the motor vehicle record points. Some records seem to have about 13 points and that is even though quite high, is skewing the data.

**Figure 4: Motor Vehicle Record Points**

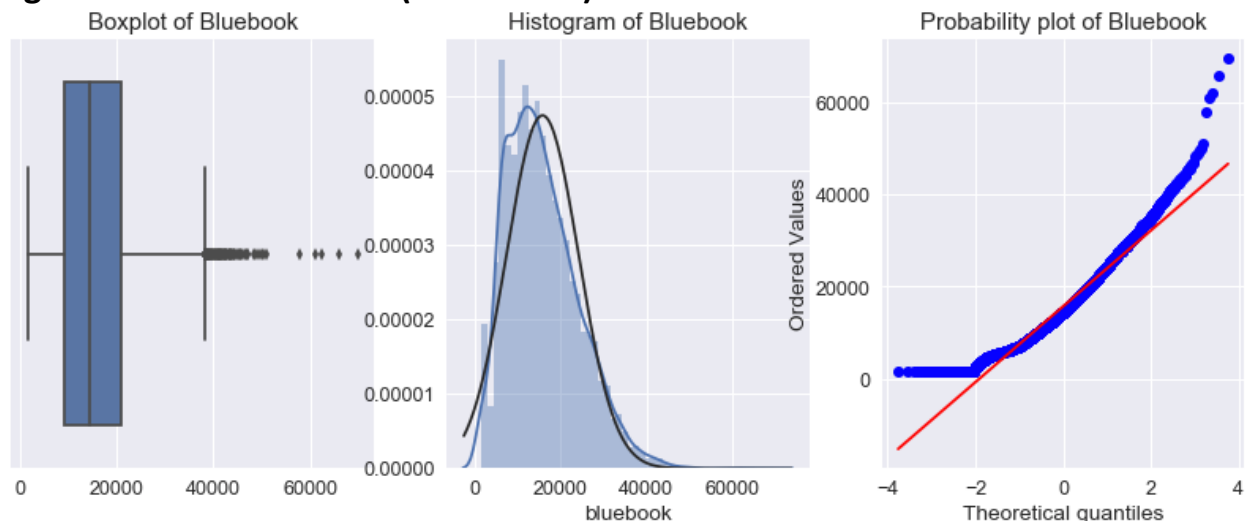

Outliers for Motor Vehicle Record Points: [13, 13]

**Figure 5: Income**

Next, I have looked at the distribution for the INCOME. This one looks quite a bit like HOME\_VAL. In case of INCOME, it has extreme values in the right tail. There are few income groups going up to 500,000. Figure 5 shows the outliers that are in the extreme group. Figure 6 shows the distribution and the outliers for the BLUEBOOK. As the figure shows there are some vehicles with value more than 60,000. It is possible that these records are correlated with the records that are in the high income group. People with high income might be more likely to buy expensive cars.

**Figure 6: Value of Vehicle (BLUEBOOK)**

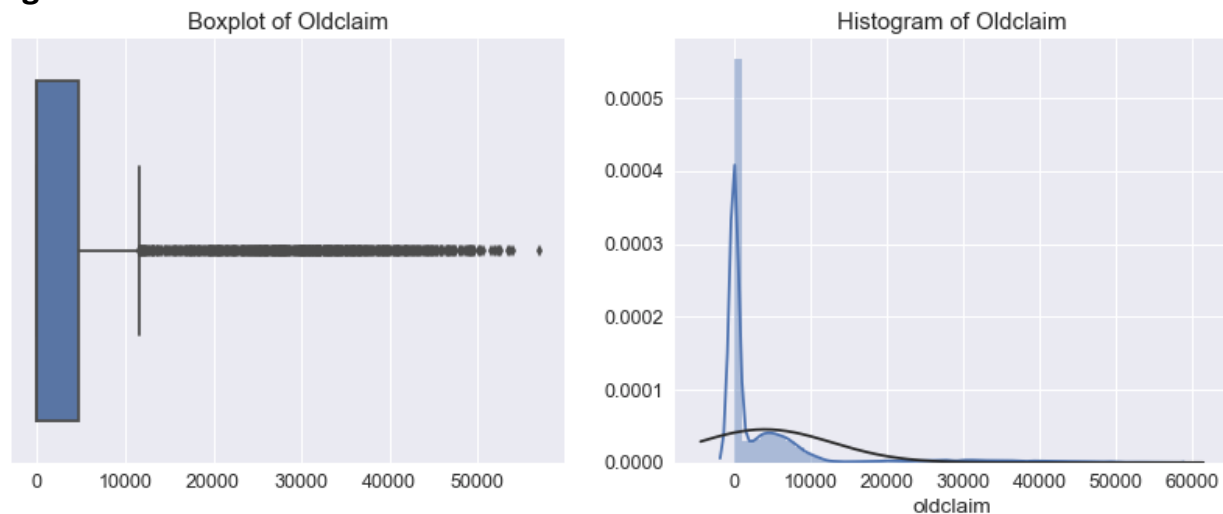

Outliers for Bluebook: [65970, 62240, 57970, 61050, 69740]

Next, I have looked at the OLDCLAIM as part of the final continuous variable. As shown in Figure 7, this variable has the quite interesting distribution compared to the others. There are many records with 0 claims meaning there are many people did not have past claims. Also data seems to be distributed into three different categories. First category is people without any old claims, second category is the people that are between 0 to 11000. And the final category is where people with claim that is worth more than the 11000. And the last category seems to go up all the way to 60000. We will consider this fact when we do the data extraction.

**Figure 7: Old Claims**

For categorical, first I have looked at the Red Car vs. car in the crash and the claim frequency. From the Figure 8, it is evident that there is no effect of the car color in number of crashes reported. Although there seems to be a slight increase in the claims for red color car, but that may be just due to the number of red color cars within the dataset.

**Figure 8: Red Car**

Figure 9 shows the comparison for Sex vs. car in crash and the claim frequency. As shown in the figure females may have more crashes reported, but the males seem to be high in the claim frequency.

**Figure 9: Male vs. Female**

Next in the categorical variable is driving children in a household. From the figure 10, it shows that as the number of kids increase in the household, the number of crashes seem to be increasing. However, claim frequency seems to be evenly distributed between the families without kids and the families with the kids.

**Figure 10: Driving Children**

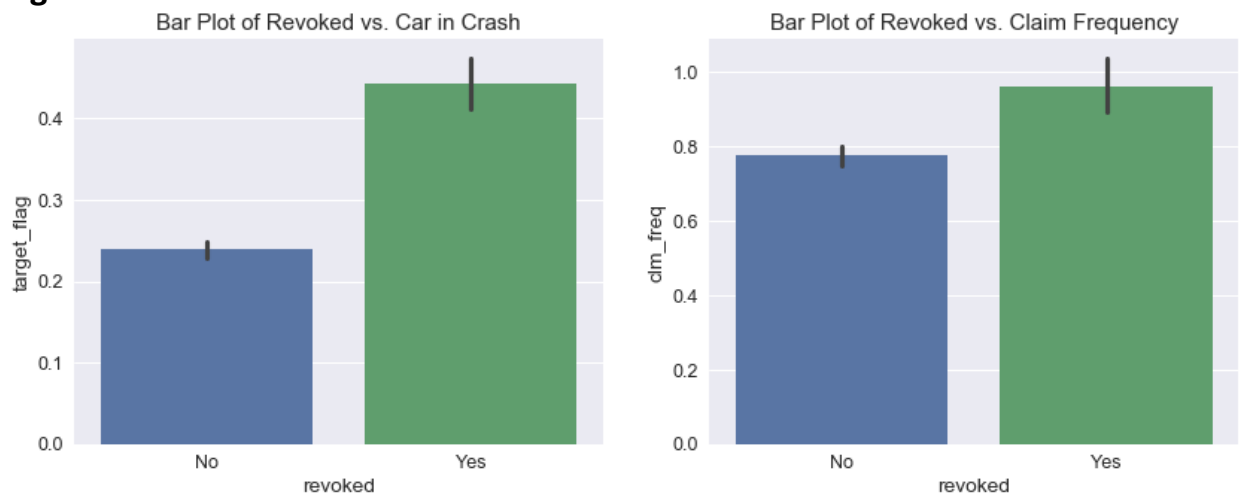

Figure 11 shows the comparison for the car types. From the chart it is evident that the sports car stands out for the number of crashes and followed by the pickup and the SUV. Claim frequency seems to even out across all the car types.

**Figure 11: Car types**

Finally, Figure 12 shows the comparison for the Revoked variable. From the chart it is clear that the people with revoked license seems to be more involved in the crash and the they had high claim frequency than the other group of people. It definitely makes sense to consider this variable when we fit the models.

**Figure 12: Revoked**

As part of the data preparation, first thing I have performed is to fix the missing values. I have decided to use the median value to replace all the missing values for each variable. For all the outliers, instead of dropping them I chose to use the truncating strategy based off of quantiles. For the variables listed above, if any values exceeded the 99th percentile, then they were replaced with the value of the 99th percentile. Likewise, for values less than the 1th percentile. Instead of replacing the data in the existing variables, I chose to create new variables with IMP\_\* for the imputed value and m\_\* to represent the existence of the data. Finally, with missing values imputed and outliers mostly fixed, it was important to remember to do these same actions with the test data. As such, I imputed missing data with the medians from the training data and truncating the variables using the original 99th and 1th percentiles of the same variables from the training set.

As discussed above, I have binned OLDCLAIM into three different buckets. First bucket representing people without any claims, second bucket representing with claims from 0 to 11000 and the last bin containing the claims more than 11000.

## Models

I have created several different models with different features set. However, I am listing the three models that seems to be interesting in terms of their performance.

### Model 1: clm\_freq & mvr\_pts

The first logistic regression I have created is solely using two features, claim frequency and the motor vehicle record points. The results from the logistic regression are shown below. Although this model considers only two features, it is performing quite well. ROC curve area of 0.67 is also pretty decent.

**Table 4: Model 1 Summary**

Logit Regression Results

**Figure 14: Model 1 ROC Curve**

## **Model 2: Top Five**

For the next model, I have considered the top five highly correlated variables with the response variable. The variables include, Claim Frequency, Motor Vehicle Record Points, Urban or City, Revoked and Single Parent. These are selected because they needed very little imputation. This model performed much better than the previous model. ROC curve area spiked to 0.73 and the AIC & BIC values are improved as well and the Pseudo R-square value is fairly low. All the five variables are statistically significant. The coefficient values match the expected theoretical effect and all the selected features should increase one's probability of getting into crash. Model 2 results and the ROC curve is listed below.

**Table 5: Model 2 Summary**

**Figure 15: Model 2 ROC Curve**

### **Model 3: Statistically Significant**

For the last model, I have considered all the imputed and original variables that are statistically significant at alpha level 0.5. Both the bluebook and imputed home value are log transformed. Out of all the models, this model performed best and this has very minimal multicollinearity problem. This model ROC curve area scored little above 0.81 and both the AIC & BIC values are decreased.

**Figure 16: Model 3 ROC Curve**

## Model Selection

The following table shows the comparison for all the models that are described above. Based on all the three models summary, I chose the model 3 as the best performing one based on its AIC and BIC values and also based on the ROC curve area value.

**Table 8: Model Comparison**

	Model 1	Model 2	Model 3
ROC	0.67	0.73	0.81
AIC	8898	8277	7358
BIC	8919	8319	7505
Pseudo R-Squared	0.056	0.122	0.223

## Model Explanation (P\_TARGET\_FLAG)

In this section we will talk about the above selected model for predicting P\_TARGET\_FLAG.

Most of the variables chosen for this model based on their statistical significance at alpha 0.05.

As explained during the EDA, each car type had some sort of effect on the car crash and the claim frequency. Hence each type has been considered separately in the model building. Also five variables have been created by imputing the value of Single Parent, Car use, marital status, and the revoked status. For all the missing data, median has been used and for the missing job information, new category "Missing Job Info" has been created. And then rest of job information has been split into different categories. IMP\_urbanicity represents whether the

person lives in the urban or not. IMP\_revoked indicates whether the person's license has been revoked or not. Also for the old claims, I have taken only the one that had few claims.

$$\begin{aligned} P\_TARGET\_FLAG = & 4.96 + 0.39 * car\_type[T.Panel Truck] + 0.51 * car\_type[T.Pickup] + 0.94 * \\ & car\_type[T.Sports Car] + 0.59 * car\_type[T.Van] + 0.71 * car\_type[T.z\_SUV] + 0.41 * kidsdriv + \\ & 0.09 * mvr\_pts - 0.05 * tif + 0.01 * travtime + 2.29 * IMP\_urbanicity + 0.98 * IMP\_revoked - \\ & 0.45 * IMP\_mstatus + 0.71 * IMP\_car\_use + 0.46 * IMP\_parent1 - 0.31 * home\_own - 0.5 * \\ & university\_degree - 0.51 * white\_collar + 0.57 * hadFewOldClaim - 0.35 * log\_bluebook - 0.45 \\ & * log\_IMP\_home\_val \end{aligned}$$

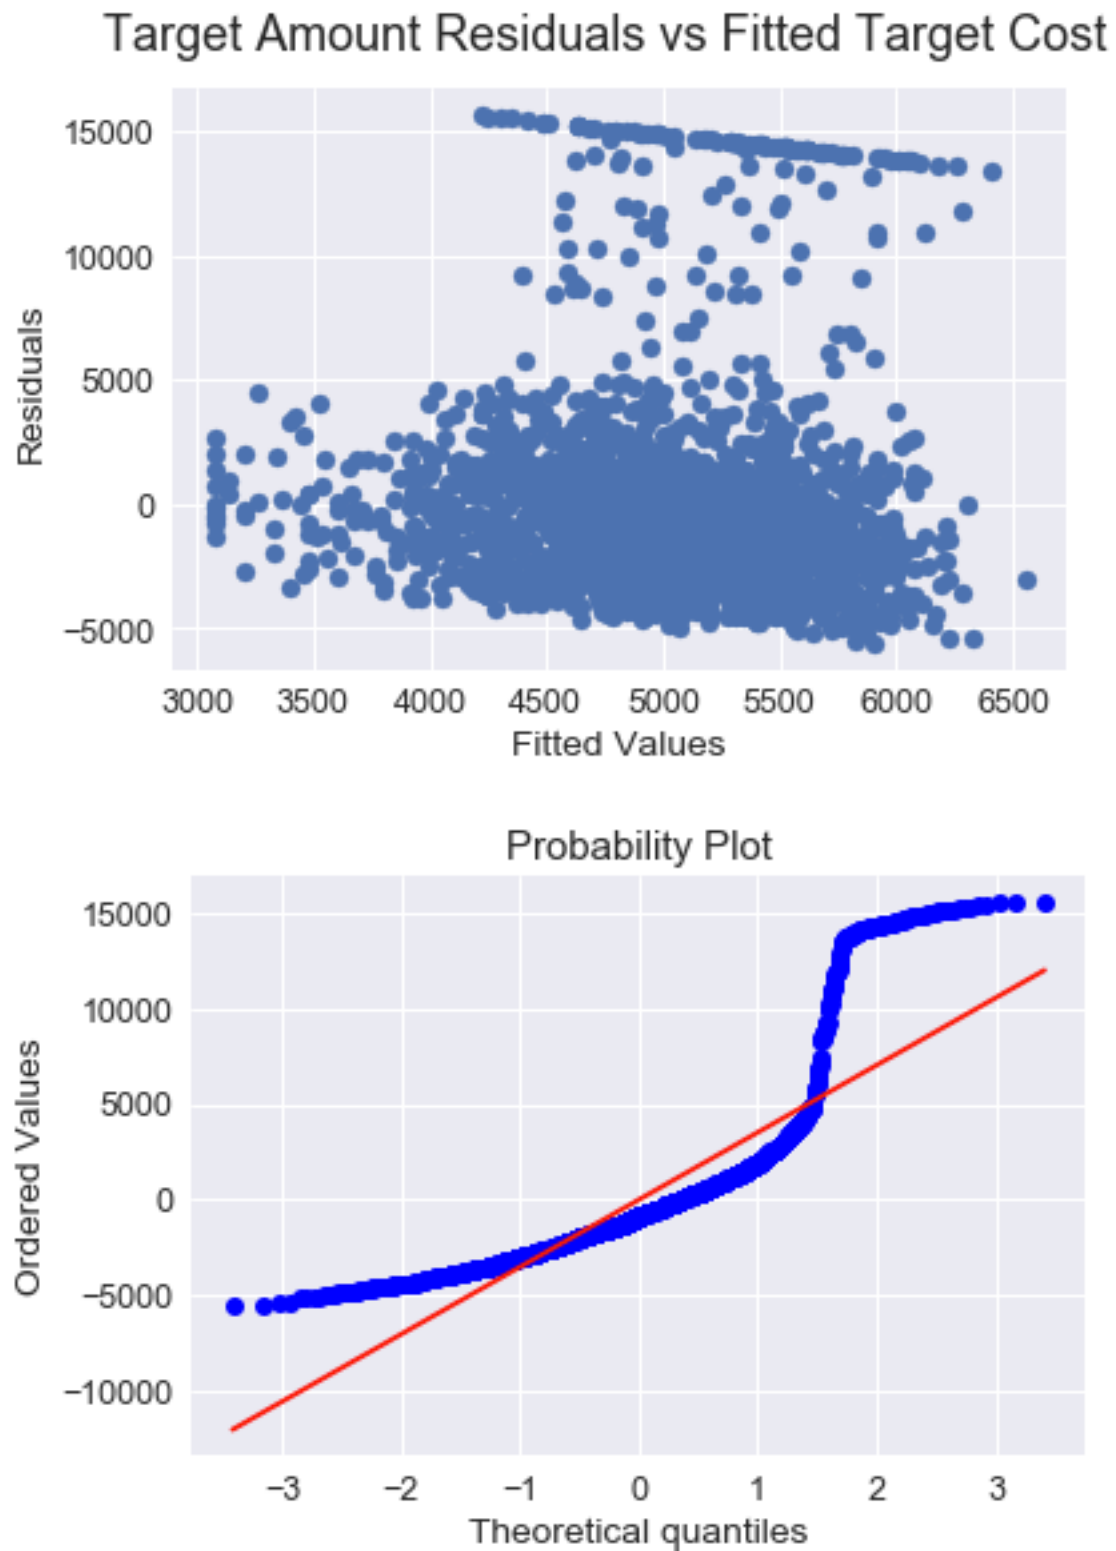

## Model Explanation (P\_TARGET\_AMT)

In this model, we predict the amount it costs if the person gets into the crash. The target amount is zero if the person did not crash their car. But if they did crash their car, this number will be a value greater than zero. I have created a simple OLS regression model, instead of using the mean to predict this amount. Based on the correlation between the features and the target variable, I chose Blue book, marital status and the motor vehicle record points. Based on this, the following table shows the results of the OLS model.

### Table 8: Target Amount Model

Dep. Variable:	target_amt	R-squared:	0.019			
Model:	OLS	Adj. R-squared:	0.018			
Method:	Least Squares	F-statistic:	14.07			
Date:	Sat, 17 Feb 2018	Prob (F-statistic):	4.41e-09			
Time:	03:02:47	Log-Likelihood:	-20940.			
No. Observations:	2153	AIC:	4.189e+04			
Df Residuals:	2149	BIC:	4.191e+04			
Df Model:	3					
Covariance Type:	nonrobust					
	coef	std err	t	P> t	[0.025	0.975]

Omnibus:	979.439	Durbin-Watson:	2.011			
Prob(Omnibus):	0.000	Jarque-Bera (JB):	4316.894			
Skew:	2.230	Prob(JB):	0.00			
Kurtosis:	8.313	Cond. No.	142.			

Figure 17: Residual plots

log\_bluebook is the natural logarithm of a person's vehicular bluebook value. mvr\_points are the number of motor vehicle record points a person has. Finally, IMP\_mstatus should be 1 if a person is married, else 0. Although this model's AIC and BIC are quite high, it did perform better compared to the mean score. The QQ plot show in Figure 17 that they are not following the normal distribution.

$$P\_TARGET\_AMT = -2113.39 + 764.31 * \log\_bluebook - 402.41 * IMP\_mstatus + 63.94 * mvr\_pts$$

## Conclusion

The objective of this assignment was to create a model that predicts best which customers are most likely to crash their cars. And if the person did get into crash, predict the amount that will cost. I have created several logistic regression models with the data provided. For the logistic regression it requires significant amount of data preparation. During the EDA and the data preparation phase, I have noticed that almost all the variables seem to play some of sort of the role in predicting the response variable. This means all the variables can be taken forward into the model. However, that produced a quite complex model and suffered from the poor prediction. I think some iterations of transformation can be carried out to refine the feature list for building the better model. From what I have seen out of all the models built, third model seems to be the best of all.
